Hyperkyphotic Posture Predicts Mortality in Older Community-Dwelling Men and Women: A Prospective Study

Deborah M. Kado, MD, MS^{*}, Mei-Hua Huang, DrPH^{*}, Arun S. Karlamangla, MD, PhD^{*}, Elizabeth Barrett-Connor, MD and Gail A. Greendale, MD^{*}

Objectives: To determine the association between hyperkyphotic posture and rate of mortality and cause-specific mortality in older persons.

Design: Prospective cohort study.

Setting: Rancho Bernardo, California.

Participants: Subjects were 1,353 participants from the Rancho Bernardo Study who had measurements of kyphotic posture made at an osteoporosis visit between 1988 and 1991.

Measures: Kyphotic posture was measured as the number of 1.7-cm blocks that needed to be placed under the participant's head to achieve a neutral head position when lying supine on a radiology table. Demographic and clinical characteristics and health behaviors were assessed at a clinic visit using standard questionnaires. Participants were followed for an average of 4.2 years, with mortality and cause of death confirmed using review of death certificates.

Results: Hyperkyphotic posture, defined as requiring one or more blocks under the occiput to achieve a neutral head position while lying supine, was more common in men than women (44% in men, 22% of women, $P < .0001$).

In age- and sex-adjusted analyses, persons with hyperkyphotic posture had a 1.44 greater rate of mortality (95% confidence interval (CI)=1.12 1.86, $P=.005$). In multiply adjusted models, the increased rate of death associated with hyperkyphotic posture remained significant (relative hazard=1.40, 95% CI=1.08 1.81, $P=.012$). In cause-specific mortality analyses, hyperkyphotic posture was specifically associated with an increased rate of death due to atherosclerosis.

Conclusion: Older men and women with hyperkyphotic posture have higher mortality rates.
